

POST-AI IDE EXTENSION

Software quality and cost control do not come by chance.

Control Room is the developer cockpit for supervising AI-executed software work inside VS Code.

Mission -> Task Graph -> Evidence -> Human Interleaving

The problem

AI can write more code. Developers still need to know what happened.

Chat output does not equal control.

Today, complex agent work collapses into long text streams, messy terminal logs, and unclear claims. It can also get overwhelmingly expensive very fast.

For serious engineering teams, the missing layer is visibility, verification, and interruption.

● Lost context

● Unclear state

● Low trust

The workflow is changing

From direct editing to objective definition, automated execution, and supervision.

Control Room turns AI coding from a chat interaction into an operational loop a developer can supervise.

The product

A lightweight VS Code extension, not a new IDE fork.

Built where developers already work.

Control Room sits on top of VS Code: editor, terminal, file explorer, language servers, Git, and existing setups remain intact.

The product adds the orchestration layer: visual graph, evidence, pause/resume, and local state.

Core unit of value

Not Chat -> File -> Diff. Control Room is Mission -> Task Graph -> Evidence -> Interleaving.

Cursor-like tools optimize editing.

Great for inline help and one-thread conversations.

Cost control by model selection

Control Room optimizes supervision.

Built for multi-step work, blockers, verification, and human control.

Explorable evidence

Every agent claim must come with receipts.

Done means inspectable.

When a task finishes, Control Room links the result to exact files, line ranges, diffs, terminal output, and verification results.

The developer clicks a node and lands at the precise code or log line that supports the claim.

Human interleaving

The agent runs the loop until the developer needs to steer.

Pause

Stop execution safely

Take the Wheel

Developer fixes, edits, inspects

Resume

Agent continues with updated context

This is not replacement. It is supervised execution with fast manual intervention.

Why this matters to investors

The wedge is narrow, painful, and expanding.

Pain

Complex AI coding work is hard to track and trust.

Timing

Agentic coding is moving from novelty to daily workflow.

Distribution

Start as a VS Code extension with low adoption friction.

Moat

Evidence, state, task graphs, and interleaving compound into workflow data.

MVP path

Prove one painful workflow before broadening.

1

Local prototype

State files, task graph, execution loop, evidence log

2

VS Code UI

Sidebar, webview graph, task detail, evidence links

3

Interleaving runtime

Pause safely, detect human edits, resume with context

4

Verification polish

Better diffs, command outputs, verification state

First demo workflow: refactor backend auth across multiple files, verify, intervene, resume, and inspect evidence.

Control Room

A serious developer interface for supervising AI-executed engineering work.

Define. Monitor. Verify. Interrupt. Resume.

The opportunity is not another chatbot. The opportunity is the control layer for agentic software development.
